Dear Springer:

The lung fluke just came in with the morning mail. I haven't as yet looked over Manter's keys of the lung flukes, but seeing in Walton's lists of trematodes of amphibians that *Pneumobites longiplexus* (Stafford, 1902) Ward 1917 had been taken from *Rana c. eryllio* among other frogs I checked on the genus *Pneumobites* in Ward and Whipple. Like *Pneumonoces* this genus has a large seminal vesical (Plagiorchiidae; Plagiorchiinae) and has its genital pore near the oral sucker. Where *Pneumonoces* has the testes in tandem these lie side by side, well lateral, in *Pneumobites*. There are two other amphibian flukes in the genus which have not been taken in grylio regions so that *P. longiplexus* seems to be a good name at least provisionally for your Florida forms.

I'm glad to get the verification of the *Bufo peltacephalus* identification. Is there chance of getting any more of them? How about *Microhyla* and *Eleutherodactylus* at present?

I see Ross Allen has a note on the yellow-lipped snake in the most recent *Copeia*.

Sincerely yours,
